

# Collision-induced absorption of radiation by interacting molecules

Katharine L. C. Hunt

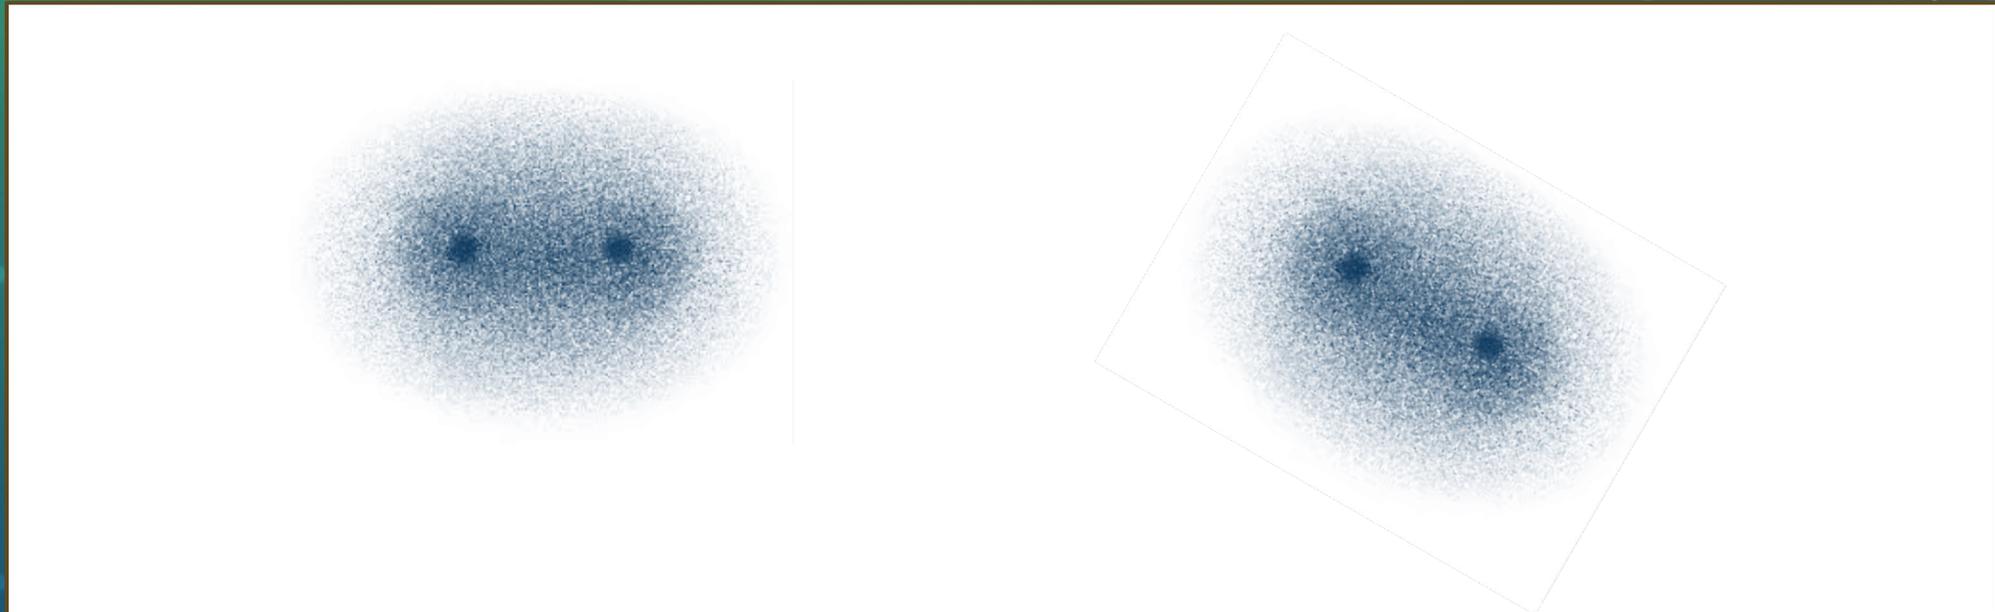

Department of Chemistry, Michigan State University

Institute for Advanced Studies, Department of Physics and Materials Science,  
University of Luxembourg

Physics Seminar, November 24, 2023

Interactions between molecules during a collision induce transient dipoles. The interactions break the symmetry of non-dipolar species. The induced dipoles change as the molecules rotate and vibrate, leading to collision-induced absorption in the infrared and far infrared.

Collision-induced absorption has been extensively studied experimentally at and below room temperature, in samples of hydrogen, nitrogen, methane, and other molecules.

Information on collision-induced dipoles is needed for astrophysical applications.

- Anomalous radiative profile of very old, very cool white dwarf stars.
- Formation of the first stars in the universe?
- Temperature profiles of the outer planets and exoplanets.

The Pillars of Creation, a star-forming region in the Eagle Nebula

A vibrant Hubble Space Telescope image of the S106 star-forming region in the constellation Cygnus. The image shows a complex of interstellar clouds in shades of blue, cyan, and orange, with numerous bright stars scattered throughout. The clouds are illuminated by the light of young stars, creating a rich, multi-colored scene. The stars exhibit prominent diffraction spikes, characteristic of Hubble's resolution.

NASA/ESA Hubble view of the star-forming region in S106, in Cygnus

How did the first stars form? Star formation is believed to occur in cool, dense regions of molecular hydrogen. As a primordial gas cloud contracts under gravity, it heats up. A cooling mechanism is needed to permit the gas cloud to continue to contract.

and M. A. Kuhn, *Astrophys. J.*  
**787**, 109 (2014).  
NASA, CXC/PSU/JPL-Caltech

NGC 2024 in the Flame Nebula

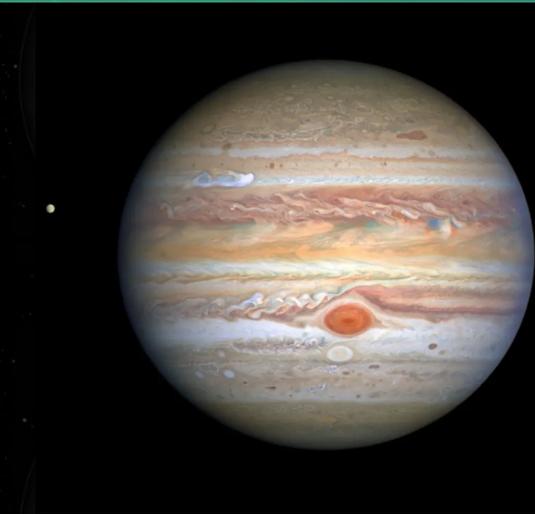

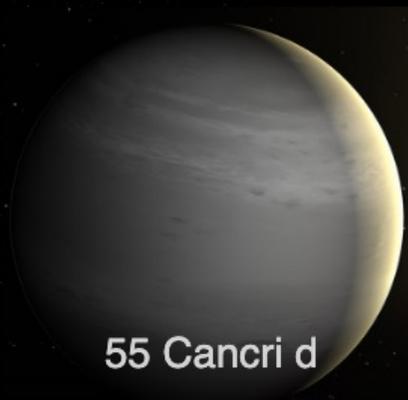

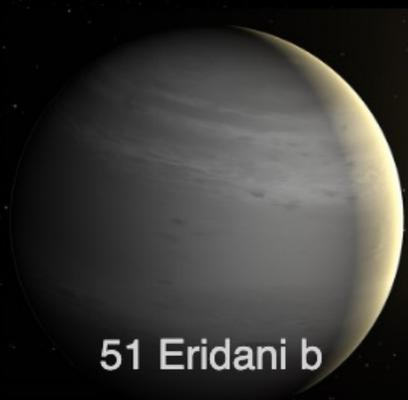

When  $\text{H}_2$ , H, HD, and He are in their ground electronic states, vibrational or rotational transitions are necessary to cool the gas further, to permit star formation. The predicted size of the Population III stars depends on the efficiency of cooling. Size estimates range from  $M_{\odot}$  to  $1000 M_{\odot}$ .

Dipole moments in the y and z directions, as a function of the angle  $\theta$  between the  $H_2$  bond axis and the intermolecular vector. Results from  $0^\circ$  to  $90^\circ$  from *ab initio* calculations, remainder obtained by symmetry arguments  
H.-K. Lee, X. Li, E. Miliordos, and K. L. C. Hunt, *J. Chem. Phys.* **150**, 204307 (2019).

## Spherical Tensor Analysis of the Dipole

$$\mu^M(r, R, \theta) = 4\pi/3^{1/2} \sum_{\lambda, L, m} D_{\lambda L}(r, R) \langle \lambda L m M - m | 1 M \rangle Y_{\lambda}^m(\theta, \phi) Y_{L}^{M-m}(0, 0)$$

Correspondence with Cartesian tensor elements

$$\mu^0(r, R, \theta) = \mu_z(r, R, \theta)$$

$$\mu^1(r, R, \theta) = - (1/2)^{1/2} [ \mu_x(r, R, \theta) + i \mu_y(r, R, \theta) ]$$

$$\mu^{-1}(r, R, \theta) = (1/2)^{1/2} [ \mu_x(r, R, \theta) - i \mu_y(r, R, \theta) ]$$

Advantages: This illuminates the physical mechanisms that contribute to the dipole. This form is also very useful in spectroscopic line shape calculations.

# Physical mechanisms of dipole induction for $\text{H}_2 \cdots \text{H}$

The leading long-range contribution comes from the quadrupole-induced dipole

This contribution varies as  $R^{-4}$  in the separation of  $\text{H}_2$  and H

It shows up in the spherical tensor expansion coefficient  $D_{23}$

Hexadecapolar induction is also apparent in the *ab initio* results

This contribution varies as  $R^{-6}$  in the separation of  $\text{H}_2$  and H

It shows up in the spherical tensor expansion coefficient  $D_{45}$

Dispersion and back-induction are also apparent in the *ab initio* results

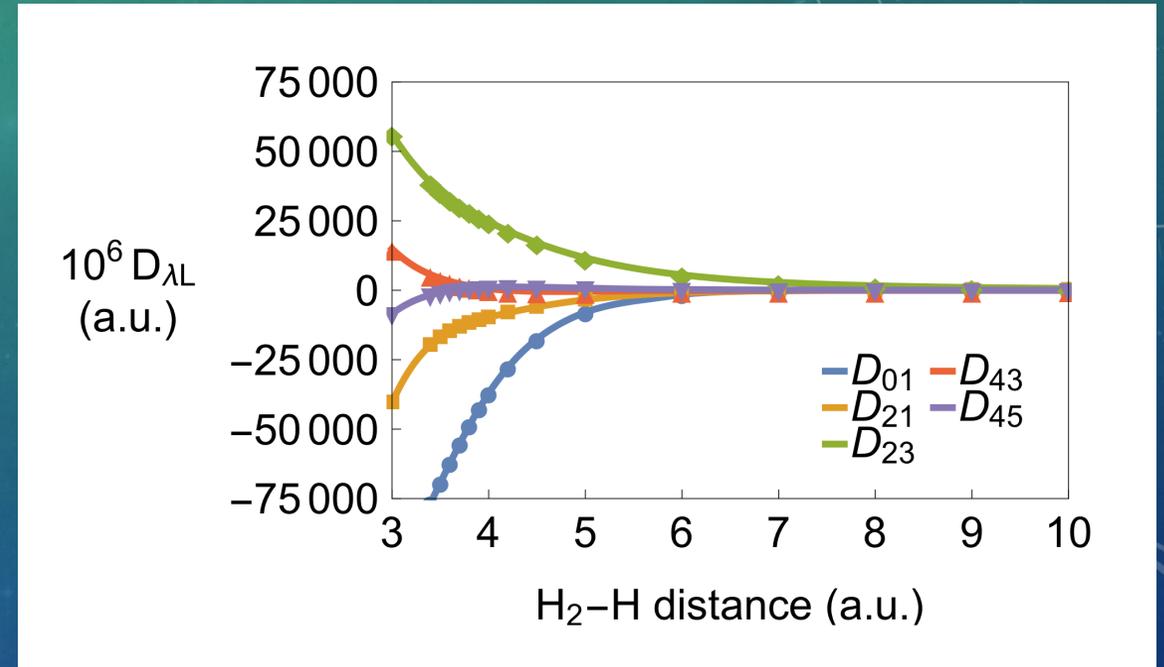

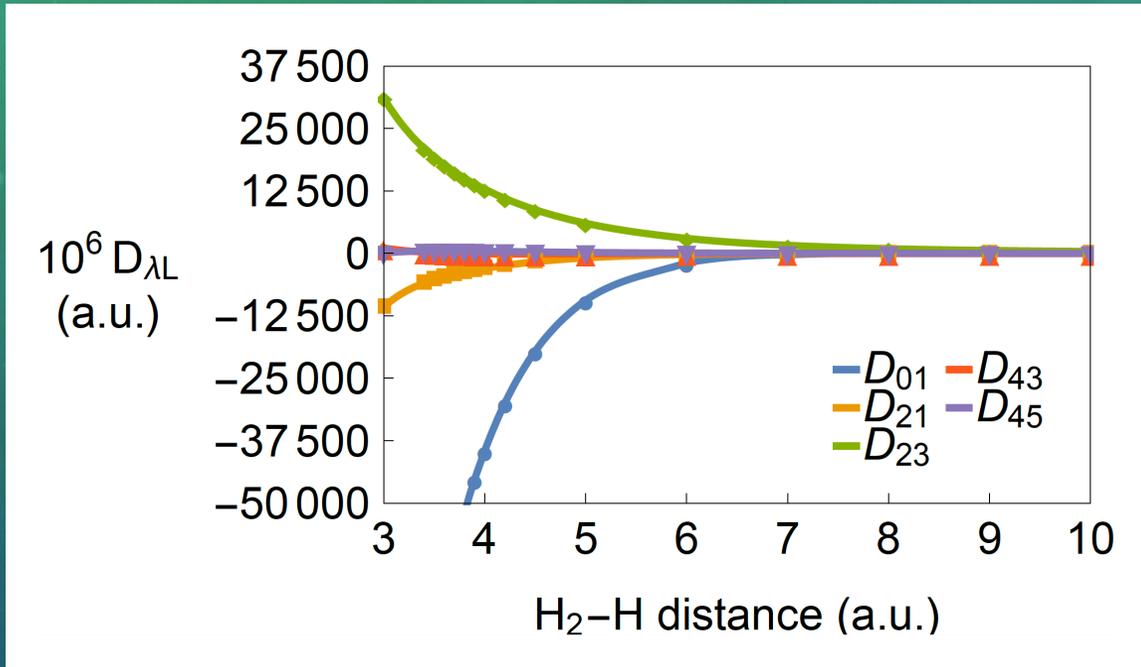

These contributions vary as  $R^{-7}$  in the separation of  $\text{H}_2$  and H

They are evident in  $D_{01}$ . They are present in other coefficients, but harder to detect there

$D_{21}$  and  $D_{43}$  have no long-range classical counterparts, but they contribute significantly at shorter range

# Results for Spherical Tensor Components

$$\mu^M(r, R, \theta) = 4\pi/3^{1/2} \sum_{\lambda, L, m} D_{\lambda L}(r, R) \langle \lambda L m M - m | 1 M \rangle Y_{\lambda}^m(\theta, \phi) Y_L^{M-m}(0, 0)$$

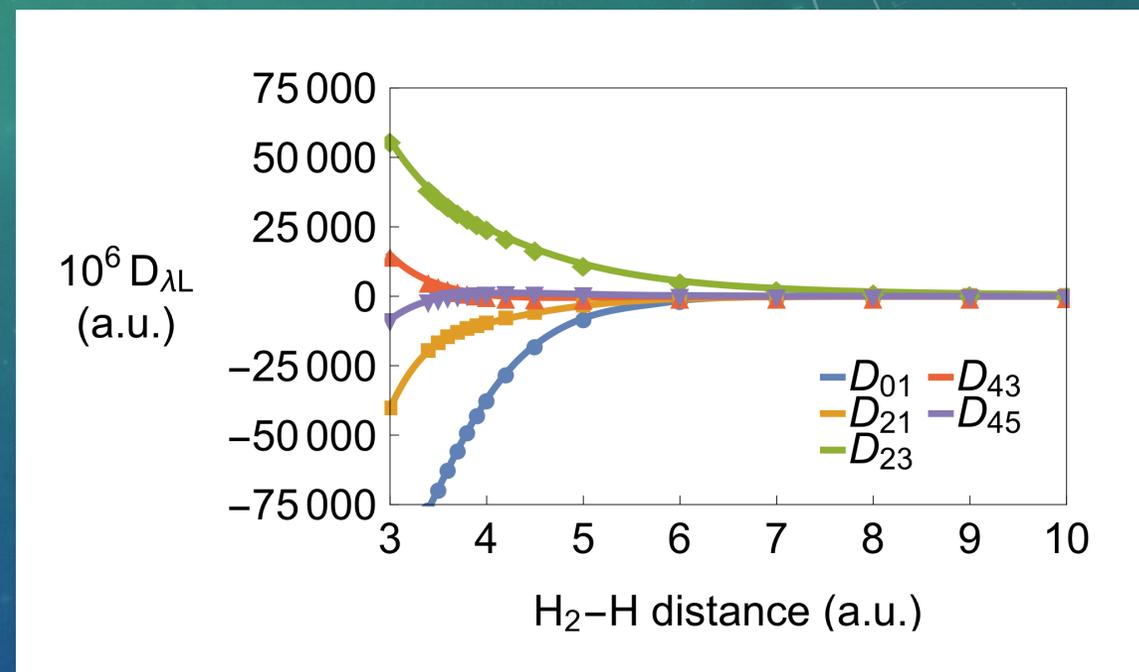

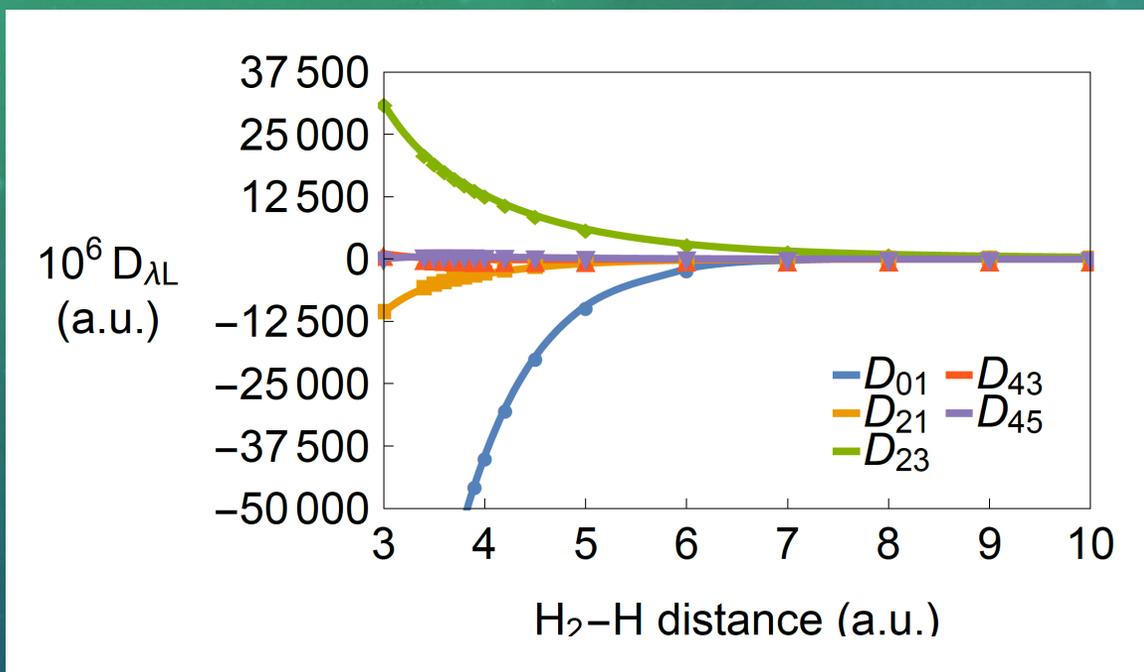

Results for the leading expansion coefficients. The largest coefficients are  $D_{01}$  and  $D_{23}$ . As the separation  $R$  decreases,  $D_{21}$ ,  $D_{43}$ , and  $D_{45}$  grow in relative magnitude.

H.-K. Lee, X. Li, E. Miliordos, and K. L. C. Hunt, *J. Chem. Phys.* **150**, 204307 (2019).

# Dependence of Spherical Tensor Components on Bond Length

$$\mu^M(r, R, \theta) = 4\pi/3^{1/2} \sum_{\lambda, L, m} D_{\lambda L}(r, R) \langle \lambda L m M - m | 1 M \rangle Y_{\lambda}^m(\theta, \phi) Y_L^{M-m}(0, 0)$$

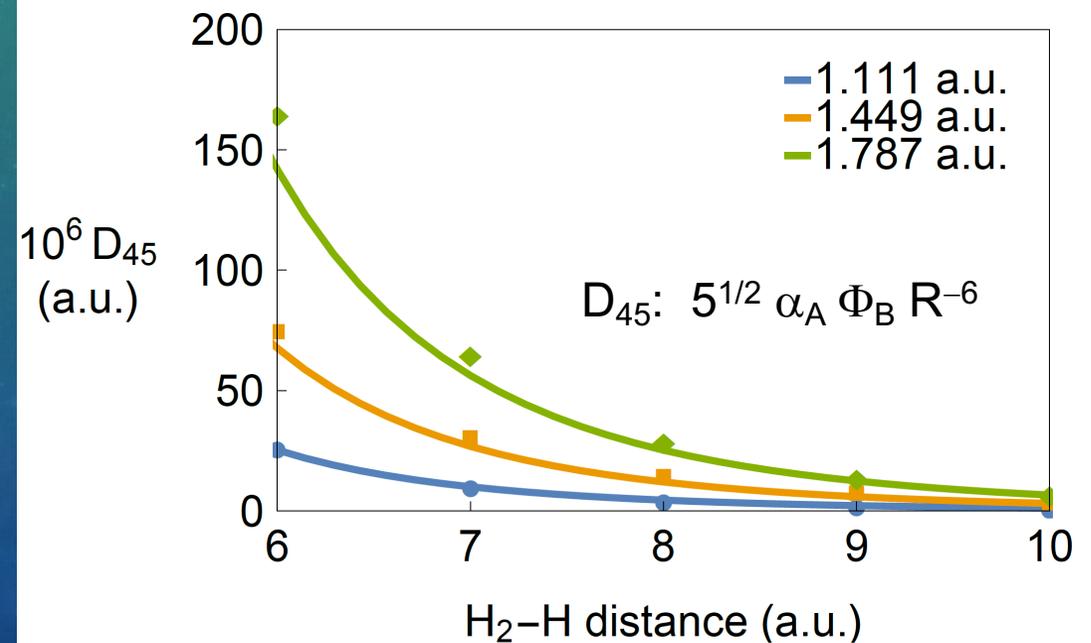

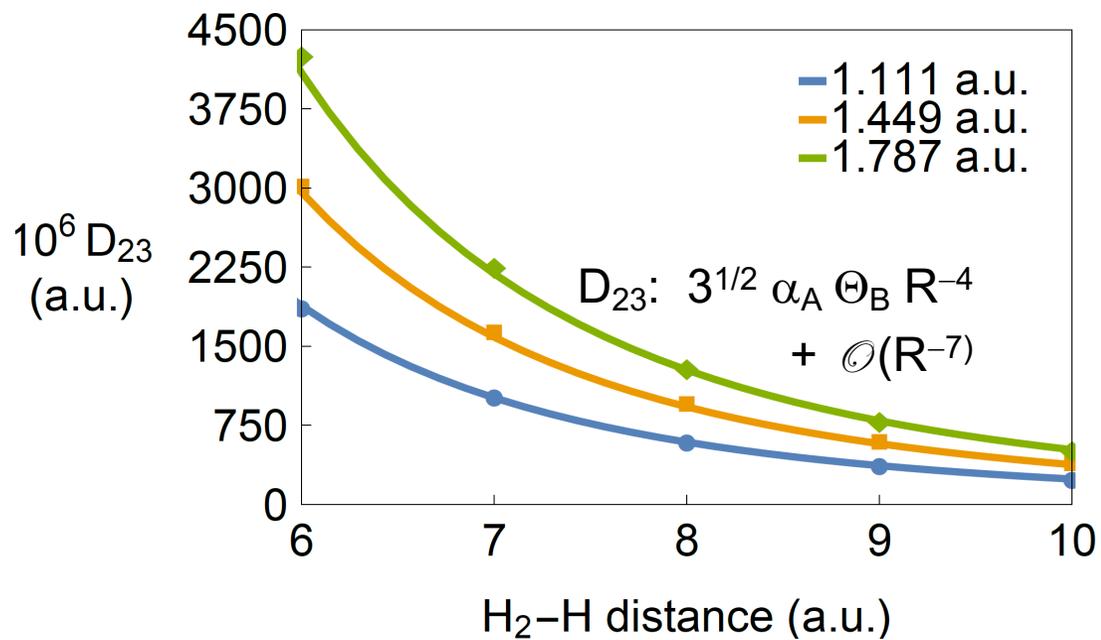

The largest coefficients are  $D_{01}$  and  $D_{23}$ . As the bond length increases,  $D_{21}$ ,  $D_{43}$ , and  $D_{45}$  grow in relative magnitude

# Comparison with Known Long-Range Forms

$$\mu^M(r, R, \theta) = 4\pi/3^{1/2} \sum_{\lambda, L, m} D_{\lambda L}(r, R) \langle \lambda L m M - m | 1 M \rangle Y_{\lambda}^m(\theta, \phi) Y_L^{M-m}(0, 0)$$

Largest coefficients:  $D_{01}$  and  $D_{23}$ . As  $r$  increases,  $D_{21}$ ,  $D_{43}$ , and  $D_{45}$  grow.

## Dispersion dipoles of unlike pairs A and B

- $\mu_{\text{disp}}^{\text{AB}} = - \left. \partial \Delta E^{\text{AB}}_{\text{disp}} / \partial \mathbf{F} \right|_{\mathbf{F} \rightarrow 0}$
- Spontaneous, quantum mechanical fluctuations in the charge density of molecule A set up a nonuniform local field at B.

$$F^{\text{A}}(\omega) = T^{(2)}(\mathbf{R}) \cdot \mu_{\text{fl}}^{\text{A}}(\omega) + (1/3) T^{(3)}(\mathbf{R}) : \theta_{\text{fl}}^{\text{A}}(\omega) + \dots$$

$$F'^{\text{A}}(\omega) = - T^{(3)}(\mathbf{R}) \cdot \mu_{\text{fl}}^{\text{A}}(\omega) + \dots$$

- The local field induces charge moments in B, as determined by the **field-dependent** susceptibilities of B and the nonuniformity of the local field.

Reaction field theory for  $\Delta E_{\text{vdW}}$ :

B. Linder, *Adv. Chem. Phys.* **12**, 225 (1967).

D. Langbein, *Theory of van der Waals Attraction* (Springer, New York, 1974) Chapter 3.

Theory of the dispersion dipole:

K. L. C. Hunt and J. E. Bohr, *J. Chem. Phys.* **83**, 5198 (1985).

- The Induced dipole is

$$\mu_{\text{ind}}^{\text{B}}(\omega) = \alpha^{\text{B}}(\mathbf{F}, \omega) \cdot \mathbf{F}^{\text{A}}(\omega) + (1/3) \mathbf{A}^{\text{B}}(\mathbf{F}, \omega) : \mathbf{F}'^{\text{A}}(\omega) + (1/\omega) \mathbf{G}'^{\text{B}}(\mathbf{F}, \omega) \cdot \mathbf{B}^{\text{A}}(\omega) + \dots$$

- The induced polarization in B gives rise to a nonuniform local field at A, the reaction field:

$$\mathbf{F}^{\text{B}}(\omega) = \mathbf{T}^{(2)}(\mathbf{R}) \cdot \mu_{\text{ind}}^{\text{B}}(\omega) - (1/3) \mathbf{T}^{(3)}(\mathbf{R}) : \theta_{\text{ind}}^{\text{B}}(\omega) + \dots$$

$$\mathbf{F}'^{\text{B}}(\omega) = \mathbf{T}^{(3)}(\mathbf{R}) \cdot \mu_{\text{ind}}^{\text{B}}(\omega) + \dots$$

- The resulting change in the energy of molecule A is the average of the instantaneous energy shift over fluctuating charge distribution of A.

$$\Delta E^{\text{A}} = - (1/2) \langle \mu_{\text{fl}}^{\text{A}}(t) \cdot \mathbf{F}^{\text{B}}(t) \rangle - (1/6) \langle \theta_{\text{fl}}^{\text{A}}(t) : \mathbf{F}'^{\text{B}}(t) \rangle + \dots$$

- The field and field gradients from B result from the spontaneously fluctuating multipoles of A. Their correlations are given by the fluctuation-dissipation theorem, **applied to A in the field F.**

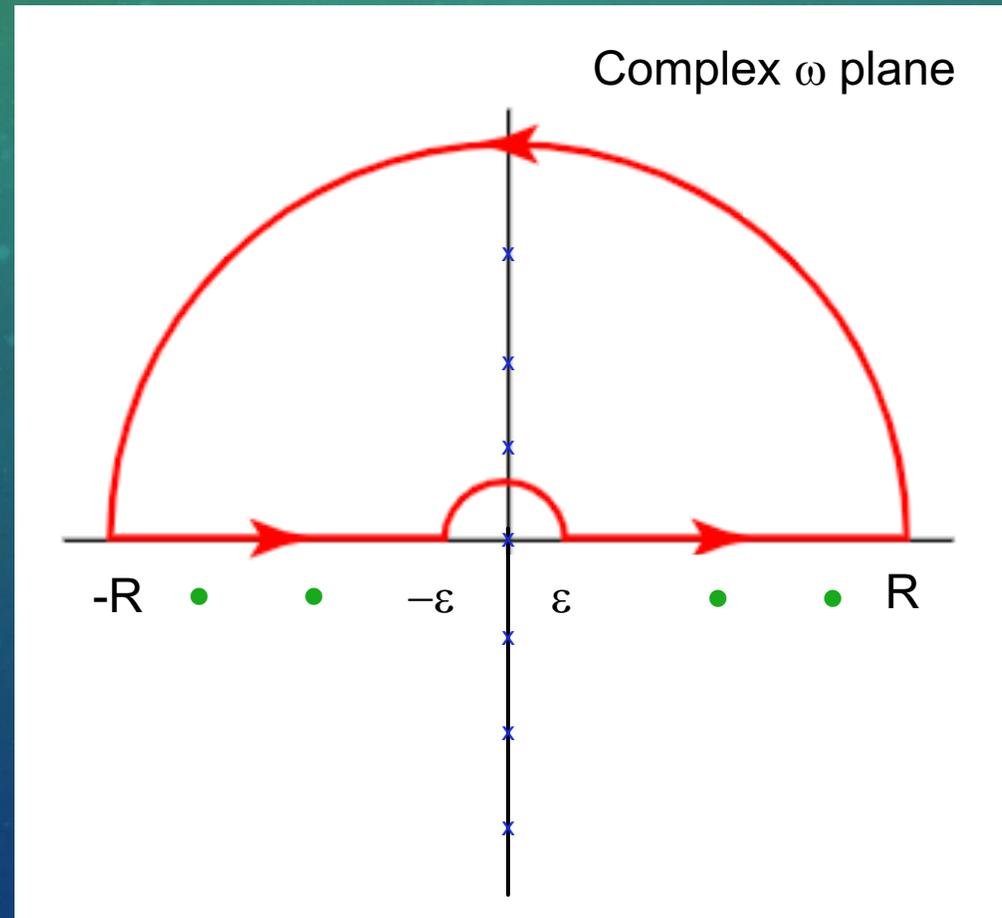

- From the fluctuation-dissipation theorem of H. B. Callen and T. Welton, *Phys. Rev.* **83**, 34 (1951), modified for static-field effects,

$$\begin{aligned} & (1/2) \langle \mu_\alpha(\omega) \mu_\beta(\omega') + \mu_\beta(\omega') \mu_\alpha(\omega) \rangle_{\mathbf{F}} \\ & = (\hbar/2\pi) \alpha''_{\alpha\beta}(\omega; \mathbf{F}) \delta(\omega + \omega') \coth(\hbar\omega/2kT) \end{aligned}$$

$$\begin{aligned} & (1/2) \langle \mu_\alpha(\omega) \theta_{\beta\gamma}(\omega') + \theta_{\beta\gamma}(r', \omega') \mu_\alpha(\omega) \rangle_{\mathbf{F}} \\ & = (\hbar/2\pi) A''_{\alpha,\beta\gamma}(r, r', \omega; \mathbf{F}) \delta(\omega + \omega') \coth(\hbar\omega/2kT) \end{aligned}$$

- The effects of a spontaneous fluctuation in the charge density of B are added.
- The net energy change is given in terms of an integral over all real frequencies.
- The real parts of the susceptibilities are even in the frequency, and the imaginary parts are odd. This permits us to write the energy change as the integral over an analytic function of  $\omega$ .

- The susceptibilities are analytic in the upper half plane, to ensure causality. Therefore, the only poles in the upper half plane come from the function  $\coth(\hbar\omega/2kT)$ . They are located along the imaginary axis at  $\omega_n = 2\pi i nkT/\hbar$ .

- Typically, the poles along the imaginary axis are sufficiently close together that the sum over the poles can be converted to an integral over imaginary frequencies.
- Then expand the susceptibilities in the field  $\mathbf{F}$ , to obtain the answer

Result for the dispersion dipole of atoms or centrosymmetric molecules:

$$\mu_{\phi}^{AB} = (\hbar/3\pi) \int_0^{\infty} d\omega T^{(2)}_{\alpha\beta}(\mathbf{R}) \alpha^B_{\beta\gamma}(i\omega) T^{(3)}_{\gamma\delta\varepsilon}(\mathbf{R}) B^A_{\alpha\phi,\delta\varepsilon}(0, i\omega) \\ - T^{(2)}_{\alpha\beta}(\mathbf{R}) B^B_{\beta\phi,\gamma\delta}(0, i\omega) T^{(3)}_{\gamma\delta\varepsilon}(\mathbf{R}) \alpha^A_{\varepsilon\alpha}(i\omega)$$

$$\alpha_{\alpha\beta}(i\omega)$$

$$B_{\alpha\beta,\gamma\delta}(0, i\omega)$$

$$T^{(2)}_{\alpha\beta}(\mathbf{R}) = \nabla_{\alpha} \nabla_{\beta} (1/R)$$

$$T^{(3)}_{\alpha\beta\gamma}(\mathbf{R}) = \nabla_{\alpha} \nabla_{\beta} \nabla_{\gamma} (1/R)$$

Specializing to the dipole for two atoms at long range

$$\mu_z^{AB} = (9\hbar R^{-7}/\pi) \int_0^\infty [ \alpha^A(i\omega) B^B(0,i\omega) - \alpha^B(i\omega) B^A(0,i\omega) ] d\omega$$

$B^X(0,i\omega)$  denotes the dipole-dipole-quadrupole hyperpolarizability of atom X

$\alpha^X(i\omega)$  denotes the polarizability of atom X

If  $\mu_z^{AB}$  is positive, the polarity of the dispersion dipole is  $A^+B^-$

Each atom is hyperpolarized by the fluctuating charge distribution of the neighboring atom, and the applied field

**The applied field alters spontaneous quantum fluctuations of the atomic charge densities**

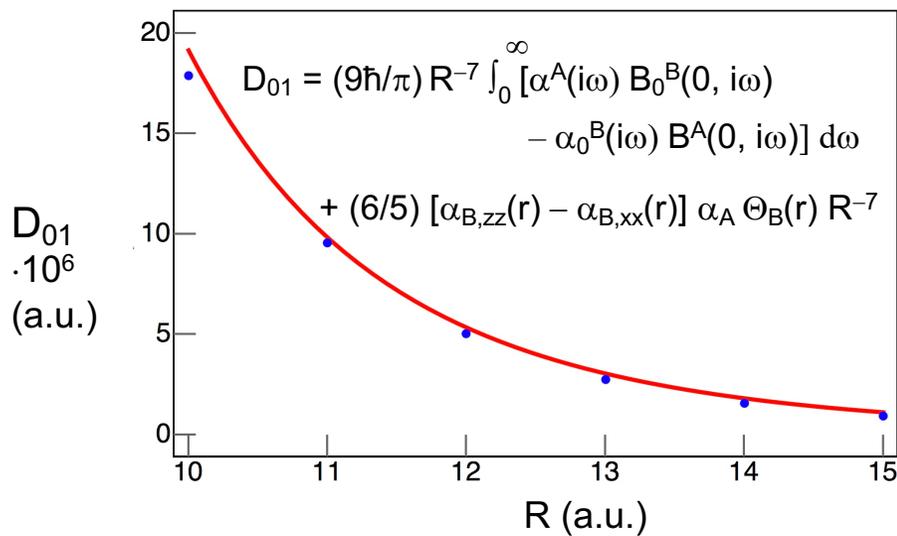

L. Galatry and T. Gharbi, *Chem. Phys. Lett.* **75**, 427 (1980).

**K. L. C. Hunt and J. E. Bohr, *J. Chem. Phys.* **83**, 5198 (1985).**

# The Dispersion Dipole in *ab initio* Quantum Calculations for $\text{H}_2 \cdots \text{H}$

$$\mu^M(r, R, \theta) = 4\pi/3^{1/2} \sum_{\lambda, L, m} D_{\lambda L}(r, R) \langle \lambda L m M - m | 1 M \rangle Y_{\lambda}^m(\theta, \phi) Y_L^{M-m}(0, 0)$$

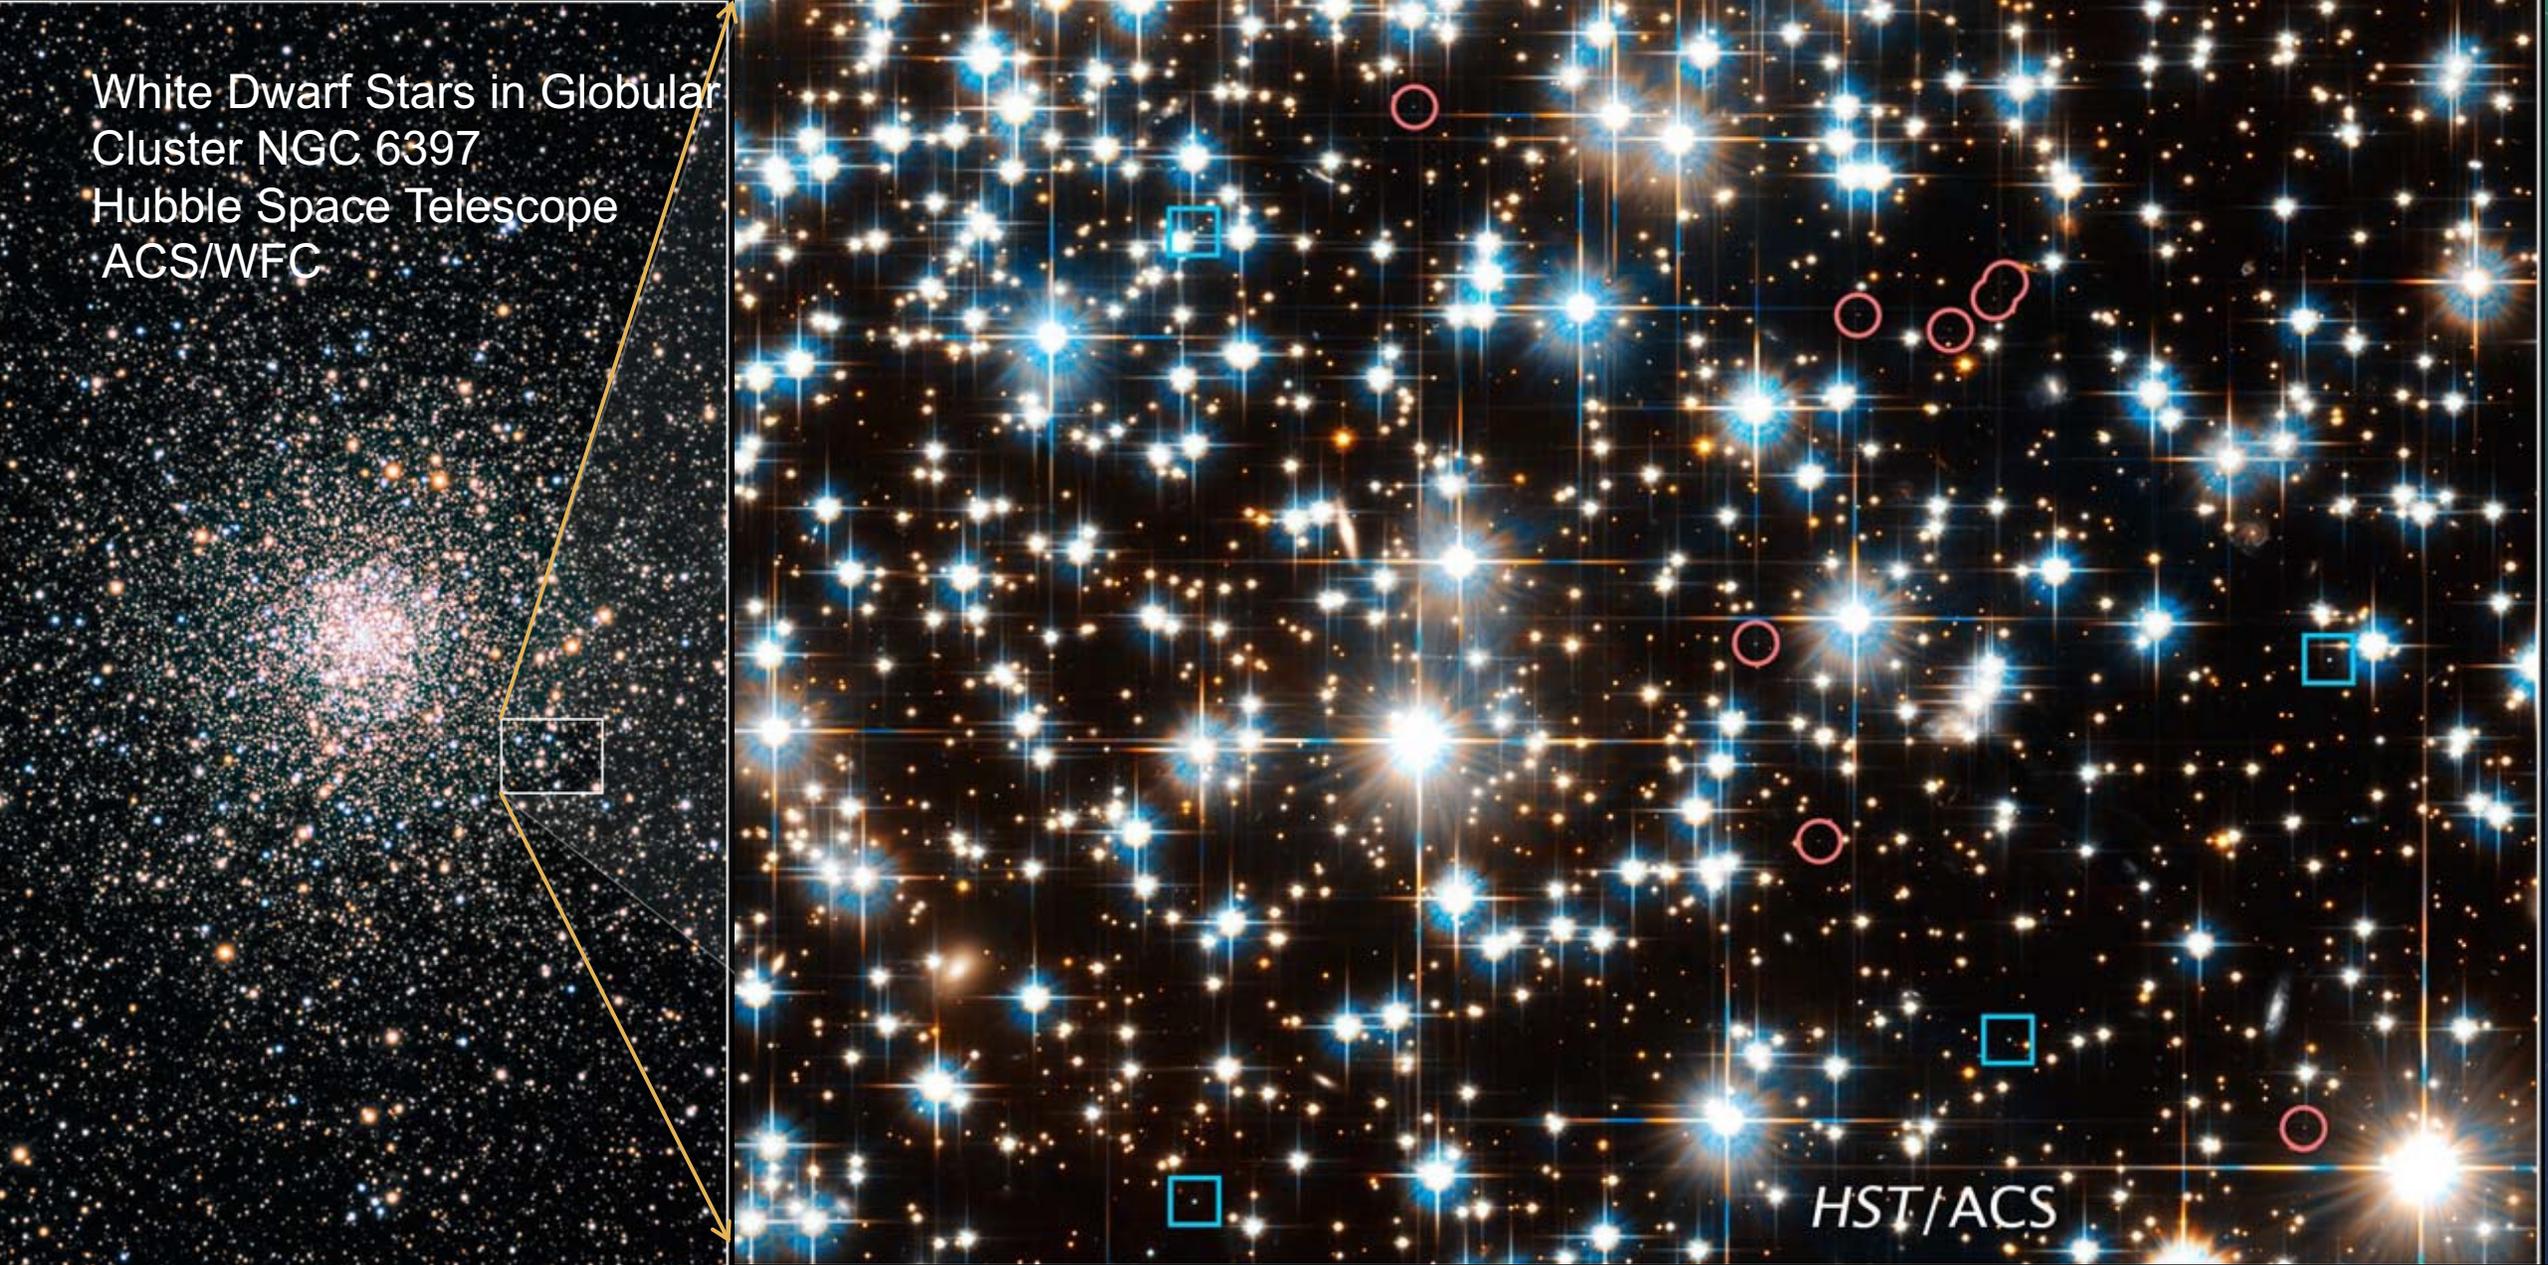

$D_{01}$  converges to the known long-range form!

## Spherical Tensor Analysis for the $\text{H}_2 \cdots \text{H}_2$ dipole

Tensor components of the dipole are expressed in terms of the spherical harmonics of the orientation angles for the bond axes and the intermolecular vector

$$\begin{aligned} \Delta\mu^M(\mathbf{r}_A, \mathbf{r}_B, \mathbf{R}) = & (4\pi)^{3/2} 3^{-1/2} \sum D_{\lambda_A \lambda_B \Lambda L}(\mathbf{r}_A, \mathbf{r}_B, \mathbf{R}) \\ & \times Y_{\lambda_A m_A}(\Omega^A) Y_{\lambda_B m_B}(\Omega^B) Y_{L M-m}(\Omega^R) \\ & \times \langle \lambda_A \lambda_B m_A m_B | \Lambda m \rangle \langle \Lambda L m M-m | 1 M \rangle \end{aligned}$$

Summation runs over  $\lambda_A, \lambda_B, \Lambda, L, m_A$  and  $m_B$

## Spectroscopic implications

$$\Delta\mu^M(\mathbf{r}_A, \mathbf{r}_B, \mathbf{R}) = (4\pi)^{3/2} 3^{-1/2} \sum D_{\lambda_A \lambda_B \Lambda L}(\mathbf{r}_A, \mathbf{r}_B, \mathbf{R}) Y_{\lambda_A m_A}(\Omega^A) Y_{\lambda_B m_B}(\Omega^B) Y_{L M-m}(\Omega^R) \\ \times \langle \lambda_A \lambda_B m_A m_B | \Lambda m \rangle \langle \Lambda L m M-m | 1 M \rangle$$

If the potential is isotropic, then

Coefficients  $D_{\lambda_A 0 \Lambda L}$  produce transitions with  $\Delta J^A = \pm \lambda_A$  and  $\Delta J^B = 0$

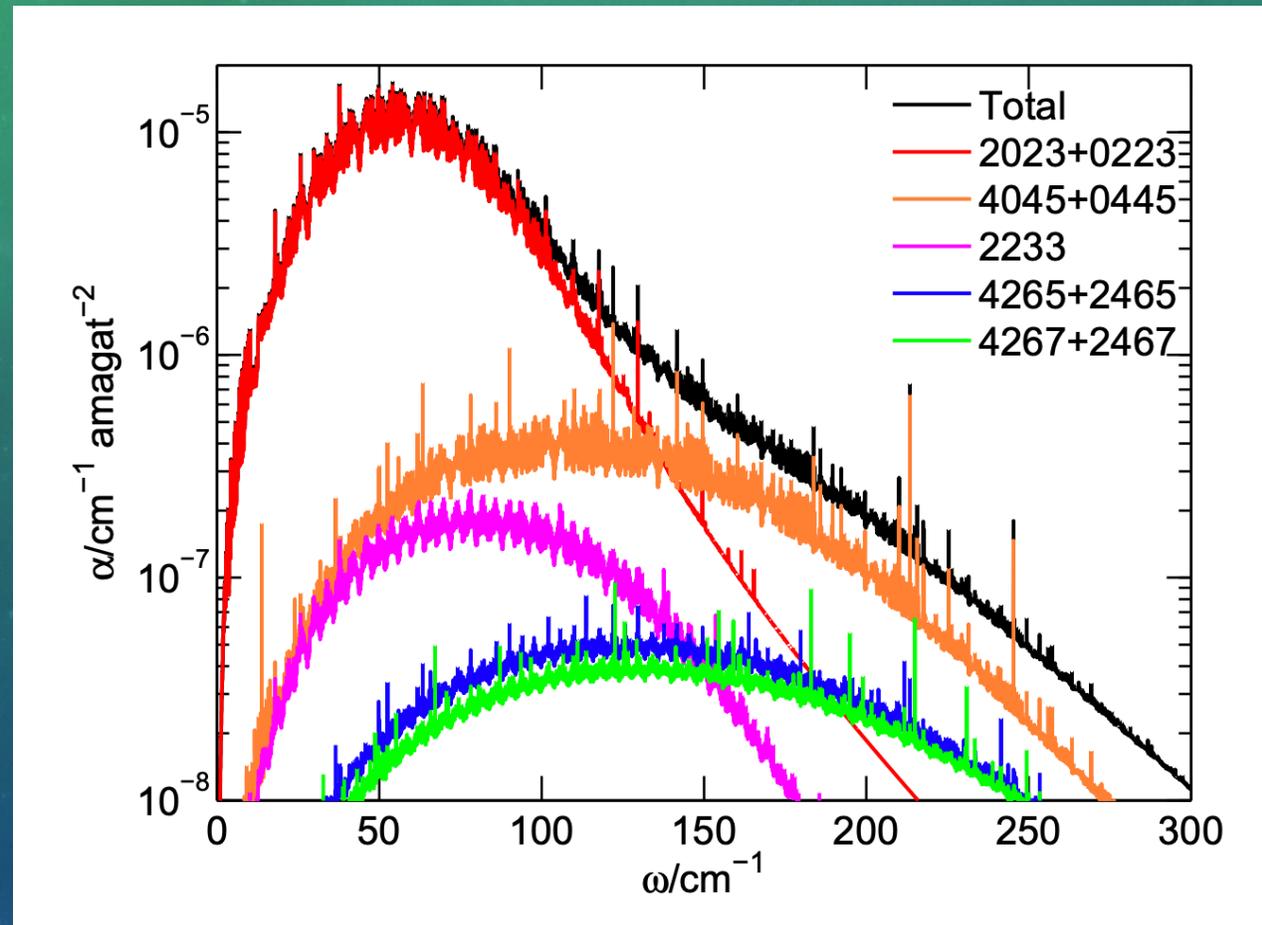

Coefficients  $D_{0 \lambda_B \Lambda L}$  produce transitions with  $\Delta J^A = 0$  and  $\Delta J^B = \pm \lambda_B$

Coefficients  $D_{\lambda_A \lambda_B \Lambda L}$  with  $\lambda_A \neq 0$  and  $\lambda_B \neq 0$  produce *simultaneous* transitions with  $\Delta J^A = \pm \lambda_A$  and  $\Delta J^B = \pm \lambda_B$

Higher  $\Delta J$  values produce absorption in the farther wings of the spectrum

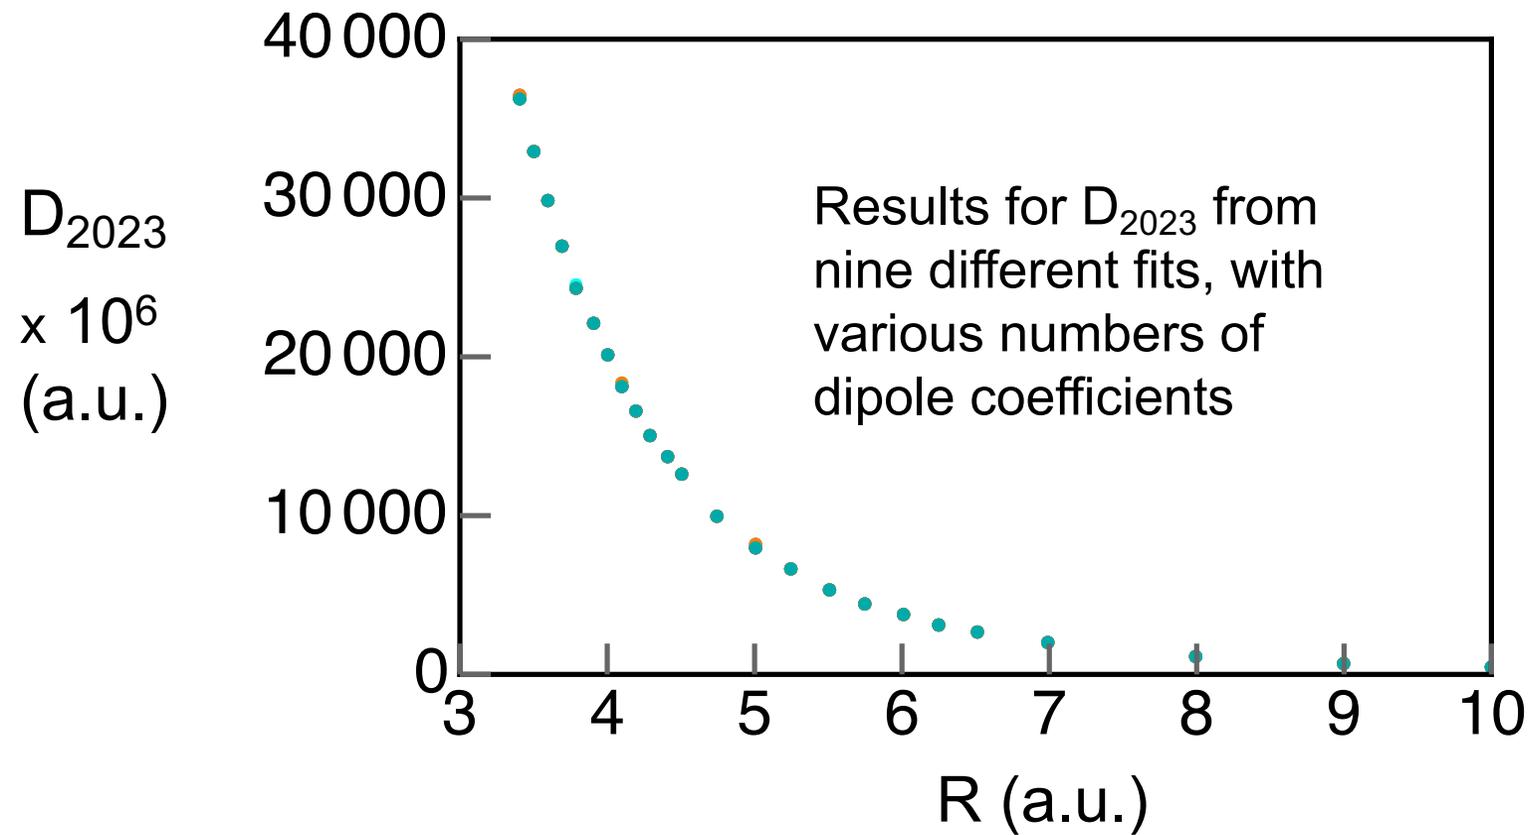

Anisotropies of the potential combine with the angular momentum indices on the dipole coefficients to produce transitions with additional  $\Delta J$  values
